Introduction to Computer Vision – Homework 2 RA192617 – Edgar Rodolfo Quispe Condori RA192618 – Darwin Ttito Concha

Institute of Computing, University of Campinas (UNICAMP) Campinas-SP, Brazil, 13083-852

1 Input data

In this project we use three different videos, the tecnical details for each video are show in table 1.

Complete result of the experiments are available at: *this link*. Successfull stabilization with keypoints matching will be download in the directory **myoutput**.

Name Time(seconds) Frames # **Problem** p2-1-0.avi 20 198 Scale p2-2-0.av 26 Translation and Rotation 260 p2-2-0.avi 10 104 Rotation

Table 1: My caption

The original videos were recorded in 30fps but we considers 10fps to reduce the experiments execution time. The size of each frame is 640×480 pixels.

2 Keypoints Detector and Descriptor

The algorithms that we implemented are based on the ORB to detect and SIFT to describe keypoints, it has slithly modification that were done based in experimental results and requested task.

2.1 Keypoints Detector

We used ORB like interest point detector. The original approach uses FAST(Features from Accelerated Segment Test) to detect interests points and assings an orientation based in the intensity centroid.

Originaly, FAST uses non-maximal suppression for removing adjacent corners and machine learning to improve the performance of the algorithm. In our implementation we do not use machine learning because the explanation is not clear. Our implementation and experiment consider three parameters :

- Threshold: this parameter define if the sixteen neighbors point are lighter, darker or similar to reference point.
- *N* : condition to determine if a point is a keypoint(at least N consecutive neighbors must be lighter or darker to reference point).
- Non-Maximum Suppression: this parameter removes adjacent corners that are too close between them.

FAST does not produce a measure of cornerness (it has large responses along edges). As similar to the original implementation of ORB we employ a Harris corner measure to order and select N keypoints. Another limitation of FAST is that it does not produce orientation. To compensate this issue we use a approach similar to SIFT(ORB use moments of the patch around the keypoint). This technique take a window around of each keypoint and collect gradient directions and magnitudes. Then, a histogram is created for this and the amount that is added to the bin of the histogram is proportional to the magnitude of gradient at each points. Also, we used a gaussian weighting function, this function is multiplied by the magnitude. The farther away, the lesser the magnitude added.

Figure 1 shows results with different parameter settings.

Acording to figure 1 we can see that with parameter threshold, the number of keypoints grows inversely proportional to its value. If we choose a too low value, we start getting falses positives and with a too big value, we start ignoring keypoints. This same effect occurs with the parameter N.

In the case of *No-Maximal Suppresssion*, it removes close keypoints, but we have found that this redundancy of keypoints is util for stabilization.

2.2 Keypoints Descriptor

The original SIFT considers a pyramid in order to be invariant to scale, the keypoint descriptor is then computed from a specific level of this pyramid. Analysing the data it is easy to see that the scale differents between adjacent frame are negligibles. Thus, in our implementation ignores this stage in order to improve the performance of the algorithm. Figure 2 shows results of the implementation.

(a) (20, 8, False). 987 keypoints detected

(c) (30, 8, False). 328 keypoints detected

(e) (40, 9, False). 24 keypoints detected

(b) (20, 8, True). 185 keypoints detected

(d) (30, 8, True). 68 keypoints detected

(f) (40, 9, True). 6 keypoints detected

Figure 1: Results of experiment with different parameter settings. The label of each subfigure follows the following format: (threshold, N, Non-maximum suppression) and the number of keypoints detected.

We can see in figure 2 that the use of Non-Maximum Suppression create more outlier(wrong matches), this is because removing points that are close to one that will be correctly match decrease the number of inliers. Our experiments suggest to use the setting of (30,8,False).

3 Match hypothesis

Our implementation considers a simple match algorithm(brute force). For each keypoints of frame i we find the closest match in the frame i+1 iterating over all possible cantidates. We compare L2 Norm and cosine metrics to measure the similarity. Note that this implementation can generate the same match for two different keypoints yielding an outlier.

And idea of improvement of performance of this algorithm is to use $KNN(K-Nearest\ Neighbors)$. For real time aplication this may be a good option because its complexity is $O(n\log n)$, while our approach is $O(n^2)$ (n is the number of keypoints).

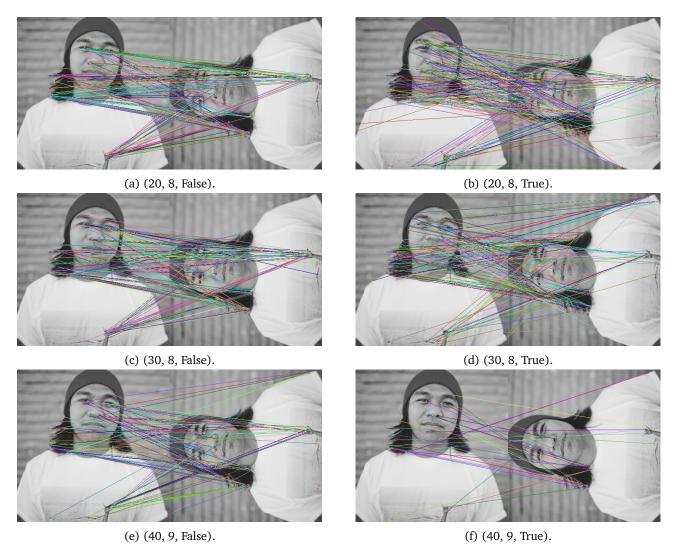

Figure 2: Results of matches with different parameter settings. The label of each subfigure follows the following format: (threshold, N, Non-maximum suppression)

Figure 3 shows the different result comparing *L2 Norm* and *cosine* metrics.

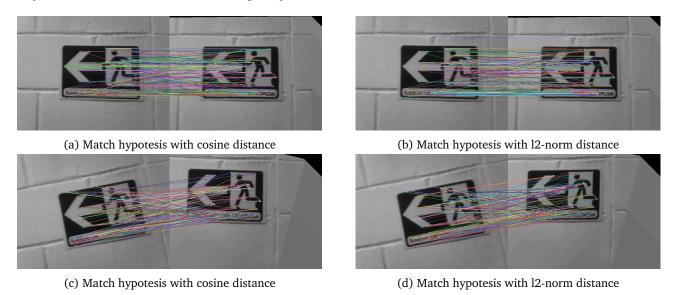

Figure 3: Comparison of match hypothesis with cosine and 12-norm

We can see in figure 3 that the result of the experiment are very similar because there is not such a extreme difference between the performance of these metrics. There is an interesting difference in the execution time, as shown in table ??. L2-norm is slithly faster.

Name	Time per frame		
Name	L2-norm	Cosine	
p2-1-0.avi	54.446	64.327	
p2-2-0.av	37.321	42.982	
p2-2-0.avi	54.446	45.262	

Table 2: Execution time comparison.

We use cosine distance as main similarity metric.

4 Affine Tranformation Fitting

Our implementation considers Affine and Projective tranformation.

The number of iteration of RANSAC has been determinated experimentaly, our implementation has the following modules:

```
def least_square(src, dst, matches, k_points, transformation = 'affine'):
def evaluate_transformation(src, dst, matches, trans_params, threshold = 1, transformation = 'affine'):
def ransac(src, dst, matches, k = 3, S = 35, threshold = 1, transformation = 'affine'):
```

• least_square: this funtion creates the matrix X, A and Y, depending of the parameter transformation. Given N points $x_i, y_i (1 \le i \le N)$, in case of affine transformation, the matrix X and Y have to rows for each point:

$$X = \begin{bmatrix} x_1 & y_1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & x_1 & y_1 & 1 \\ x_2 & y_2 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & x_2 & y_2 & 1 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ x_N & y_N & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & x_N & y_N & 1 \end{bmatrix} Y = \begin{bmatrix} x_1' \\ y_1' \\ y_1' \\ x_2' \\ y_2' \\ \vdots \\ x_N' \\ y_N' \end{bmatrix}$$

The parameters we want to find are defined for matrix A, in this case at least three points are needed and the transformation is computed using equation 1.

$$x' = ax + by + c$$

$$y' = dx + ey + f$$
(1)

$$A = \begin{bmatrix} a \\ b \\ c \\ d \\ e \\ f \end{bmatrix}$$

In the case of the projective transformation, the matrix *X* and *Y* are defined by:

$$X = \begin{bmatrix} x_1 & y_1 & 1 & 0 & 0 & 0 & -x_1'x_1 & -x_1'y_1 \\ 0 & 0 & 0 & x_1 & y_1 & 1 & -y_1'x_1 & -y_1'y_1 \\ x_2 & y_2 & 1 & 0 & 0 & 0 & -x_2'x_2 & -x_2'y_2 \\ 0 & 0 & 0 & x_2 & y_2 & 1 & -y_2'x_2 & -y_2'y_2 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ x_N & y_N & 1 & 0 & 0 & 0 & -x_N'x_N & -x_N'y_N \\ 0 & 0 & 0 & x_N & y_N & 1 & -y_N'x_N & -y_N'y_N \end{bmatrix} Y = \begin{bmatrix} x_1' \\ y_1' \\ x_2' \\ y_2' \\ \vdots \\ x_N' \\ y_N' \end{bmatrix}$$

The parameters we want to find are defined for matrix A, in this case at least four points are needed and the transformation is computed using equation 2.

$$x' = ax + by + c - gx'x - hx'y$$

$$y' = dx + ey + f - gy'x - hy'y$$
(2)

```
A = \begin{bmatrix} a \\ b \\ c \\ d \\ e \\ f \\ g \\ h \end{bmatrix}
```

Matriz A in both cases can be computed using least square. We use numpy for easy implementation, sometimes the inverse does not exists, thus we return and empty vector.

```
x_transpose = np.matrix.transpose(X)
A = np.dot(x_transpose, X)
if np.linalg.det(A) == 0:
    print('Points', k_points, 'are not suitable for the transformation')
    return []
A = np.dot(np.linalg.inv(A), np.dot(x_transpose, Y))
return A
```

- *evaluate_transformation*: this function evaluates how many points fit correctly the compute transformation based on a threshold. The book suggests it to be between one and three. In our implementation we consider a value of two because our matches in the previous step are not perfect and we want to avoid missfitting because of outliers. The output of this function are the indexes of the points that fit the given parameters.
- ransac: this function computes the RANSAC algorithm iterating S times picking k aleatory points. Our main assumptions is that at least there is one valid solution that can be reached in S iterations. The parameter k is set to three for affine and four for proyective transformation.

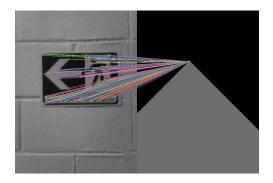

5 Transform

In order to explain our algorithm consider the following notation: i refers to the i-th frame in the original video, and i' refers to the i-th frame in the stabilized video.

Initially, we considered the following algorithm to compute i':

- 1. extract keypoints(X) from (i-1)'
- 2. extract keypoints(Y) from i
- 3. find matches(M) between X and Y
- 4. compute transformation T from M.
- 5. apply transformation T to i

With this approach, we were obtaining a lot of transformations errors(figure 4) because the differences between i and (i-1)' are complex. This happens because most of the matches are outliers, hence, RANSAC finds a transformation that is wrong yielding in these strange but nice figures 4.

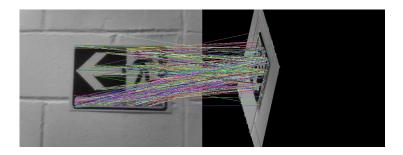

Figure 4: Errors of transformation using initial approach

Due to error described above, we defined another approach:

- 1. extract keypoints(X) from i-1
- 2. transform keypoints location of i-1 based on (i-1)'

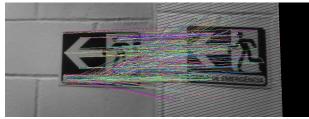

Parameters	Definition	Values
		36
S	# of iteracion of RANSAC	100
		200
Non maximun suppression	remove close keypoints	TRUE
Non maximum suppression	Telliove close keypolitis	FALSE
Distance metric	similarity between keypoints	L2-norm
Distance metric	similarity between keypoints	cosine
ORB setting(threshold, N)	keypoints detector	(30,8)
Old setting (till eshold, N)	keypoints detector	(30,12)

Table 3: Parameters evaluated.

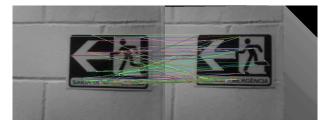

- 3. extract keypoints(Y) from i
- 4. find matches (M) between X and Y
- 5. compute transformation T from M.
- 6. apply transformation T to i

We assume that the difference between adjacent frame in the original video is small. Thus, we compare the feature vector of i and i - 1, but the keypoints location of i and (i - 1)'.

Once we have the transformation of parameters we apply it for every pixel in i, depending of the movement, some black holes and lines appears (Figure 5). Thus, we interpolate this points with the average of four neighbors and fill with zero the cases when the neighbors are also empty.

(b) With interpolation

Figure 5: Comparison of results fof transformation uisng interpolation

6 Experiments

In order to messure tha stabilization, we use MSE(min squeare error). We make experiments changing the parameters show in table 3:

6.1 S

For experiment with this parameter we set: $non-maximun\ suppression = False, distance\ metric = cosine, ORB\ setting = (30,8),$ because this configuration is the best based on previous sections.

The result of MSE and execution time(mean per frame) are shown in table 4

Name	S	MSE Execution Tir		Succesfull
	36	25921522.78	62.324	Yes
p2-1-0.avi	100	24672510.21	64.327	Yes
	200	24540916.12	62.691	Yes
p2-1-1.avi	36	44613346.37	43.003	No
	100	30052053.01	42.982	Yes
	200	29430481.39	42.4314	Yes
	36	135858245.35	46.593	No
p2-1-2.avi	100	44096547.92	45.262	Yes
	200	28768129.31	45.623	Yes

Table 4: Results for paratemer *S*.

The book suggest to set S=36, but in two cases this generates unsuccesfull stabilization, because the number of outlier is high a bigger number of iteration is needed.

In general setting a bigger value for S, results in lower MSE, moreover, when this value is duplicated the execution time grows just a little. Due to this analysis, we consider S=200 as best parameter.

6.2 Non-Maximun Suppression

For experiment with this parameter we set: $S = 200, distance \ metric = cosine, ORB \ setting = (30, 8)$. The result of MSE and execution time(mean per frame) are shown in table 5

Name	Non-maximun suppression	MSE	Execution Time	Succesfull
p2-1-0.avi	True	42818733.94	15.791	No
	False	24540916.12	62.691	Yes
p2-1-1.avi	True	2531291808.00	16.917	No
	False	29430481.39	42.431	Yes
p2-1-2.avi	True	194895992.71	13.706	No
	False	28768129.31	45.623	Yes

Table 5: Results for paratemer *Non-maximun suppression*.

We can see that the use Non-maximo suppression has a big impact, using its create to little keypoints and the stabilization is not possible. Thus we consider not to use Non-maximo suppression.

6.3 Ditance metric

For experiment with this parameter we set: $non - maximun \ suppression = False, S = 200, ORB \ setting = (30, 8)$. The result of MSE and execution time(mean per frame) are shown in table 6

Name	Ditance metric	MSE	Execution Time	Succesfull
p2-1-0.avi	L2-norm	24429436.76	54.446	Yes
	cosine	24540916.12	62.691	Yes
p2-1-1.avi	L2-norm	29964112.06	37.321	Yes
	cosine	29430481.39	42.431	Yes
p2-1-2.avi	L2-norm	24429436.76	54.446	Yes
	cosine	28768129.31	45.623	Yes

Table 6: Results for paratemer Distance metric.

From the result is seems that L2-norm is far much better than cosine, but considering that one shift of pixels location in the transformed frame can generate an error cost of 307200, this difference turns smaller. We decided use cosine.

6.4 ORB setting(threshold, N)

For experiment with this parameter we set: $non-maximun\ suppression = False, distance\ metric = cosine, S = 200.$ The result of MSE and execution time(mean per frame) are shown in table 7

Name	ORB setting(threshold, N)	MSE	Execution Time	Succesfull
p2-1-0.avi	(30,12)	2330901497.00	43.359	No
	(30,8)	24540916.12	62.691	Yes
p2-1-1.avi	(30,12)	89788339.90	29.774	No
	(30,8)	29430481.39	42.431	Yes
p2-1-2.avi	(30,12)	1185961909.67	22.773	No
	(30,8)	28768129.31	45.623	Yes

Table 7: Results for paratemer ORB setting

Similar to the Non-maximun suppresion parameter, try to generate less keypoints yields in unsuccesfull stabilization.
